Abstract:- Wavelet-Galerkin technique has very important advantages over classical finite difference and finite element method. In this paper, we have made an attempt to develop a technique for Wavelet-Galerkin solution of Neumann and mixed boundary value problem in one dimension in parallel to the work of J. Besora [5]. The Taylor’s approach has been used to include Neumann condition in Wavelet-Galerkin setup. The test examples are given to validate techniques with exact solutions.

Keywords:- Boundary Value Problems, Wavelets, Scaling Function, Connection Coefficients, Wavelet Coefficient, Wavelet-Galerkin Method.

I. INTRODUCTION

Wavelet is an important area of mathematics and now a days it becomes an important tool for applications in many areas of science and engineering.

The orthonormal bases of compactly supported wavelets for the space of square-integral function $L^2(\mathbb{R})$ was constructed by Daubechies in 1988 (see [7]). Those wavelets are bases in a Galerkin method to solve Dirichlet as well as Neumann boundary value problem. The approximations of partial differential equations with wavelet basis are more attentive, because the reality of orthogonality of compactly supported wavelets. The concepts of Multiresolution Analysis based Fast wavelet transform algorithm have given great momentum to make wavelet best approximations of ODE’s and PDE’s. Wavelet-Galerkin technique is frequently used now a days, and its numerical solution of partial differential equations have been developed by several researchers.

Many contributions have been done in the area of wavelets and differential equations by authors like Beylkin et al.[4], Jawerth et al. [9], Qian et al.[14], Qian et al. [15], Williams et al. [16], Williams et al. [19]. Several researchers now a day’s uses Daubechies wavelets as bases in a Galerkin method to solve boundary value problem. The contribution in this area is due to the remarkable work by Latto et al. [10], Xu et al. [21], [22], Williams et al. [16], [17], [18], Mishra et al [13], Jordi Besora [5] and Amartunga et al. [1], [2], [3]. It is known that the problems with periodic boundary conditions have been handled successfully. Fictious boundary approach with Dirichlet boundary conditions have been applied by Dianfeng et al. [8] in analyzing SH wave equation. Latto et al. [10] presents a connection coefficients for j=0 and N=6. The problem with Distinct boundary conditions is developed by Jordi Besora [5].

In this paper, we have proposed wavelet-Galerkin approximation to the Neumann and mixed boundary value problem, using compactly supported wavelets as basis functions introduced by Daubechies [6], [7]. We have used Taylors approach to deal with Neumann and mixed Boundary conditions.

II. WAVELETS

An oscillatory function $\psi(x) \in L^2(\mathbb{R})$ is a wavelet if it has following properties:

- $\psi(x)$ is n times differentiable and its derivatives are continuous.
- $\psi(x)$ is well localized both in time and frequency domains, i.e. $\psi(x)$ and its derivatives must decay very rapidly. For frequency localization $\hat{\psi}(\omega)$ must decay sufficiently fast as $|\omega| \to \infty$ and that $\hat{\psi}(\omega)$ becomes flat in the neighbourhood of $\omega = 0$. The flatness is associated with number of vanishing moments of $\psi(x)$, i.e.

$$\int_{-\infty}^{\infty} x^k \psi(x) \, dx = 0$$

or equivalently
\[ \frac{d^k}{d\omega^k}\hat{\psi}(\omega) = 0 \]

for \( k = 0, 1, \ldots, n \).

- in the sense that the larger number of vanishing moments more is the flatness when \( \omega \) is small.

\[ \int_{-\infty}^{\infty} |\hat{\psi}(\omega)|^2 d\omega < \infty \]

Daubechies wavelets are compactly supported functions. Since they have non zero values within a finite interval and zero values elsewhere in some intervals and they can be used for representation of solution of BVP. In order to have multiresolution properties, the scaling function is defined as \( \phi(x) \), and it must satisfy,

\[ \phi(x) = \sum_{k=0}^{L-1} a_k \phi(2x - k) \quad (1) \]

or

\[ \phi(x) = \sqrt{2} \sum_{k=-L}^{L} C_k \phi(2x - k) \; \text{with} \; \sum_{k=-L}^{L} a_k = \sqrt{2} \]

where \( L \) denotes the genus of the Daubechies wavelet. The functions generated with these coefficients will have \( \text{supp} \phi = [0, L - 1] \) and \( \left( \frac{L}{2} - 1 \right) \) vanishing wavelet moments.

![Fig.1: Daubechies Scaling function with L=6 and j=0](image)

The basic wavelet is defined in terms of scaling function by,

\[ \psi(x) = \sum_{k=-L}^{L} (-1)^k a_{1-k} \phi_k(2x - k) \quad (2) \]

A family of scaling functions is generated by translation from

\[ \phi_k(x) = \phi(x - k) \quad (3) \]

Similar a family of wavelets is denoted by translation and scaling from

\[ \psi_{j,k}(x) = \psi(2^j x - k) \quad (4) \]

Since \( \int \phi(x) dx = 1 \); the scaling function satisfies the three conditions.

1. \( \sum_{k=0}^{L-1} a_k = 2 \quad (5) \)

2. The orthonormality condition of the scaling function

\[ \int \phi(x - k) \phi(x - m) dx = \delta_{k,m} \]

Implies that

\[ \sum_{k=0}^{L-1} a_k a_{k-2m} = \delta_{0,m} \quad (6) \]
3. The moment of the smooth wavelet function to be zero.

\[
\int x^m \psi(x) dx = 0
\]

implies that

\[
\sum_{k=0}^{L-1} (-1)^k k^m a_k = 0
\]  \hspace{1cm} (7)

for \( m = 0, 1, \ldots, \frac{L}{2} - 1 \)

The relation between scaling function and wavelet function can be expressed as;

\[ V_{j+1} = V_j \oplus W_j \]

It implies that, for any integer \( m \),

\[
\int \phi(x) \psi(x - m) dx = 0 \]  \hspace{1cm} (8)

Where \( \oplus \) denotes the direct sum and \( V_j \) and \( W_j \) be the subspaces generated, respectively as the \( L^2 \)- closure of the linear spans of

\[
\phi_{j,k}(x) = 2^j \phi(2^j x - k) \quad \text{and} \quad \psi_{j,k}(x) = 2^j \psi(2^j x - k), \quad k \in \mathbb{Z}
\]

Using condition (8) we can write

\[ V_0 \subset V_1 \subset \cdots \subset V_j \subset V_{j+1} \]

And

\[ V_{j+1} = V_\oplus W_\oplus W_\oplus W_\oplus \cdots \oplus W_j \]

where \( j \) is the dilation parameter as scale. The support of the scale function \( \phi(2^j x - k) \) for a certain value of \( j \) and \( L \) is given as

\[
\text{supp} \left( \phi(2^j x - k) \right) = \left[ \frac{k}{2^j}, \frac{k+1}{2^j} \right]
\]

Each function \( f(x) \in L^2(\mathbb{R}) \), can be written in the form

\[
f(x) = \sum_k c_k \phi(2^j x - k)
\]  \hspace{1cm} (9)

and this should be satisfied the convergence property

\[
\left\| f - \sum_k c_k \phi(2^j x - k) \right\| \leq 2^{-jp} C \| f \|^p
\]

where \( c_k = \int f(x) \phi(2^j x - k) \, dx \)

and \( C \) and \( p \) are constants.

III. MULTIRESOLUTION ANALYSIS

Construction of smooth wavelets with compact support is a major task in to-day’s research scenario. Meyer[6] and Mallat [11] found conditions which we called multiresolution analysis which is use by Daubchies to construct wavelet of compact support having arbitrary smoothness.

A MRA of \( L^2(\mathbb{R}) \) is defined as a sequence of closed subspaces of \( \{ V_j \}_{j \in \mathbb{Z}} \) of \( L^2(\mathbb{R}) \) and a scaling function \( \phi \) satisfy the following conditions.

1. The space \( V_j \) are nested i.e.

\[
\cdots \subset V_{-1} \subset V_0 \subset V_1 \subset \cdots,
\]

2. The space \( L^2(\mathbb{R}) \) is a closure of the union of all \( V_j \) and the intersection of all \( V_j \) is empty. i.e.

\[
\bigcup_j V_j = L^2(\mathbb{R}) \quad \text{and} \quad \bigcap_j V_j = \{0\}
\]

3. \( f(x) \in V_j \iff f(2x) \in V_{j+1} \quad \forall \, j \in \mathbb{Z} \)

4. \( f(x) \in V_0 \iff f(x - k) \in V_0 \quad \forall \, k \in \mathbb{Z} \)

5. \( \{ \phi(x - k) \} \) is an orthonormal basis for the space \( V_0 \).

IV. WAVELET-GALERKIN METHOD

Galerkin Method was introduced by V.I Galerkin. We can discuss this using a one-dimensional differential equation.

\[
Lu(x) = f(x); \quad 0 \leq x \leq 1;
\]

where

\[
L = -\frac{d}{dx} \left( a(x) \frac{du}{dx} \right) + b(x)u(x)
\]

with boundary conditions, \( u(0) = 0 \) and \( u(1) = 0. \)
Where $a,b$ and $f$ are given real valued continuous function on $[0,1]$. We also assume that $L$ is an elliptic differential operator.

Consider, $\{v_j\}$ is a complete orthonormal basis of $L^2([0,1])$ and every $v_j \in C^2([0,1])$ such that,

$$v_j(0) = 0 \quad v_j(1) = 0$$

We can select the finite set $\Lambda$ of indices $j$ and then consider the subspace $S$.

$$S = \text{span}\{v_j; \; j \in \Lambda\}.$$ 

Approximate solution $u_x$ can be written in the form,

$$u_x = \sum_{k \in \Lambda} x_k v_k \in S$$

where each $x_k$ is scalar. We may determine $x_k$ by seeing the behaviour of $u_x$ as it look like a true solution on $S$. i.e.

$$\langle L \; u_x, \; v_j \rangle = \langle f, \; v_j \rangle \quad \forall \; j \in \Lambda, \quad (11)$$

such that the boundary conditions $u_x(0) = 0$ and $u_x(1) = 0$ are satisfied. Substituting $u_x$ values into the equation (12),

$$\sum_{k \in \Lambda} \langle \; L v_k, \; v_j \rangle x_k = \langle f, \; v_j \rangle \quad \forall \; j \in \Lambda \quad (13)$$

Then this equation can be reduced in to the linear system of equation of the form

$$\sum a_{jk} x_k = y_i$$

or

$$AX = Y \quad (14)$$

where $A = [a_{jk}]_{j,k \in \Lambda}$ and $a_{jk} = \langle L v_k, v_j \rangle$, $x$ denotes the vector $\{x_k\}_{k \in \Lambda}$ and $y$ denotes the vector $\{y_k\}_{k \in \Omega}$. In the Galerkin method, for each subset $\Lambda$, we obtain an approximation $u_x \in S$ by solving linear system (14).

If $u_x$ converges to $u$ then we can find the actual solution.

Our main concern is the method of linear system (14) by choosing a wavelet Galerkin method. The matrix $A$ should have a small condition number to obtain stability of solution and $A$ should sparse to perform calculation fast.

Similarly we can do the same thing in above set up.

Let $\psi_{j,k}(x) = 2^j \psi(2^j x - k)$ (15)

is a basis for $L^2([0,1])$ with boundary conditions

$$\psi_{j,k}(0) = \psi_{j,k}(1) = 0 \quad \forall \; j, \; k \in \Lambda \quad \text{and} \; \psi_{j,k} \in C^2.$$ 

We can replace equations (12) and (13) by

$$u_x = \sum_{j,k \in \Lambda} x_{j,k} \psi_{j,k} \quad (16)$$

and

$$\sum_{j,k \in \Lambda} \langle L \psi_{j,k}, \psi_{l,m} \rangle x_{j,k} = \langle f, \psi_{l,m} \rangle \quad \forall \; l, \; m \in \Lambda \quad (17)$$

where $A = [a_{lm,j,k}]_{(l,m),(j,k) \in \Lambda}$, $X = \{x_{j,k}\}_{(j,k) \in \Lambda}$, $Y = \{y_{l,m}\}_{(l,m) \in \Lambda}$ and $Y = Y$. Then

$$a_{lm,j,k} = \langle L \psi_{j,k}, \psi_{l,m} \rangle \quad \forall \; l, \; m, \; j, \; k \in \Lambda \quad (18)$$

where $l, m$ and $j, k$ represent respectively row and column of $A$.

This is an accurate method to find the solution of partial differential equation.

**V. CONNECTION COEFFICIENT**

To find the solution of differential equation using the Wavelet Galerkin technique we have to find the connection coefficients which is also explored in Latto et al.((10)),

$$\Omega_{11}^{d_1d_2} = \int_\Omega \phi_{11}(x) \phi_{11}(x) \; dx \quad (19)$$

Taking derivatives of the scaling function $d$ times, we get

$$\phi_{d}(x) = 2^d \sum_{k=0}^{2^d - 1} a_k \phi_{d}(2x - k) \quad (20)$$

We can simplify equation (16) then for all $\Omega_{11}^{d_1d_2}$ gives a system of linear equation with unknown vector $\Omega^{d_1d_2}$

$$T \Omega^{d_1d_2} = \frac{1}{2\pi} \Omega^{d_1d_2} \quad (21)$$

where $d = d_1 + d_2$ and $T = \sum a_i a_{i-2d+1}$. These are so called scaling equation.

But this is the homogeneous equation and does not have a unique nonzero solution. In order to make the system inhomogeneous, one equation is added and it derived from the moment equation of the scaling function $\phi$. This is the normalization equation,

$$d! = (-1)^d \sum_{l} M^{d} \Omega^{0,l}$$

Connection coefficient $\Omega^{0,l}$ can be obtained very easily using $\Omega^{d_1d_2}$. 

24
\[
\Omega^0_{l} = \int \phi_{l} \phi_{l}^2 dx = \left[ \phi_{l+1} \phi_{l+2} d_{l+2} \right]_{-\infty}^{\infty} - \int_{-\infty}^{\infty} \phi_{l+1} \phi_{l+2} d_{l+2} + 1 dx
\]

As a result of compact support wavelet basis functions exhibit, the above equation becomes

\[
\Omega^d_{l} = -\int_{-\infty}^{\infty} \phi_{l+1} \phi_{l+2} d_{l+2} + 1 dx
\]

After d integration,

\[
\Omega^d_{l} = \int_{-\infty}^{\infty} x \phi_{l}(x) dx
\]

The moments \( M^k_l \) of \( \phi_l \) are defined as

\[
M^k_l = \int_{-\infty}^{\infty} x^k \phi_l(x) dx
\]

With \( M^0_l = 1 \)

Latto et al derives a formula as

\[
M^m_l = \frac{1}{2^{(2^m-1)}} \sum_{i=0}^{m} \sum_{l=0}^{\frac{m}{2}} \sum_{t=0}^{l} a_i t^{-l} \]

Where \( a_i \)'s are the Daubechies wavelet coefficients. Finally, the system will be

\[
\left[ T - \frac{1}{2^d I} \right] \Omega^d_{l}^d \phi_{l+1} = \left[ \begin{array}{c} 0 \\ \vdots \\ 0 \end{array} \right]
\]

Matlab software is used to compute the connection coefficient and moments at different scales. Latto et al [10] computed the coefficients at \( j=0 \) and \( L=6 \) only. The computation of connection coefficients at different scales have been done by using the program given in Jordi Besora [5]. The scaling function at \( j=0 \) and \( L=6 \) connection coefficient prepared by Latto et al [10] is given in Table 1 and Table 2 respectively.

VI. TEST PROBLEMS

Consider

\[
\frac{d^2u(x)}{dx^2} + \beta u(x) = f \tag{22}
\]

Now we use Wavelet-Galerkin method solution

Here, we consider \( L=6 \) and \( j=0 \)

We can write the solution of the differential equation (22) is,

\[
u(x) = \sum_{k=L-1}^{j} c_k 2^j \phi(2^j x - k), \quad x \in [0,1]
\]

\[
\sum_{k=-5}^{1} c_k \Phi(x - k), \quad x \in [0,1]
\tag{23}
\]

where \( c_k \) are the unknown constant co-efficient

Substitute (23) in (22) we get

\[
\frac{d^2}{dx^2} \sum_{k=-5}^{1} c_k \Phi(x - k) + \beta \sum_{k=-5}^{1} c_k \Phi(x - k) = 0
\]

Taking inner product with \( \Phi(x - k) \)

We have

\[
\sum_{k=-5}^{1} c_k \Omega[n - k] + \beta \sum_{k=-5}^{1} c_k \delta_{nk} = 0
\tag{24}
\]

where

\[
\Omega[n - k] = \int \phi^*(x - k)\phi(x - n) dx
\]

\[
\delta_{nk} = \int \phi(x - k)\phi(x - n) dx
\]

By using Neumann Boundary conditions

\[
u(0) = 1; \quad u(1) = 0
\]

Considering left and right boundary conditions we can write

\[
u(0) = \sum_{k=-5}^{1} c_k \phi(-k) = 1 \tag{25}
\]

\[
u(1) = \sum_{k=-5}^{1} c_k \phi(1 - k) = 0 \tag{26}
\]

We use Taylors method to approximate derivative on the right side
Wavelet–Galerkin Solution for Boundary Value problems

\[ u(x) = u(a) + hu'(a) + \frac{h^2}{2!} u''(a) + \cdots \]

which gives the approximation of derivative at the boundary using forward, backward or central differences. Equation (25) and (26) represent the relation of the coefficient \( c_k \).

We can replace first and last equations of (24) using (25) and (26) respectively. Then we can get the following matrix with \( L=6 \)

\[
\begin{bmatrix}
0 & \phi(4) & \phi(3) & \phi(2) & \phi(1) & 0 & 0 \\
\Omega[1] & \Omega[0] & \Omega[-1] & \Omega[-2] & \Omega[-3] & \Omega[-4] & \Omega[-5] \\
\Omega[2] & \Omega[1] & \Omega[0] & \Omega[-1] & \Omega[-2] & \Omega[-3] & \Omega[-4] \\
0 & 0 & p(1) & p(2) & p(3) & p(4) & 0
\end{bmatrix} = B
\]

\[
T = \begin{bmatrix}
\Omega[1] \\
\Omega[2] \\
\Omega[3] \\
\Omega[4] \\
\Omega[5] \\
0
\end{bmatrix}
\]

\[
p(1) = \phi(4) - \phi(4-h) \\
p(2) = \phi(3) - \phi(3-h) \\
p(3) = \phi(2) - \phi(2-h) \\
p(4) = \phi(1) - \phi(1-h)
\]

\[
C = \begin{bmatrix}
c_{-5} \\
c_{-4} \\
c_{-3} \\
c_{-2} \\
c_{-1} \\
c_0 \\
c_1
\end{bmatrix}
\quad \text{and} \quad B = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}
\]

1. Suppose given Boundary Value Problem is,

\[ u_{xx} = -2 \tag{27} \]

with boundary conditions \( u(0) = 1 \) and \( u'(1) = 0 \)

The exact solution is,

\[ u(x) = -x^2 + 2x + 1 \]

\[ c_{-5} = -0.997475258266510 \]

\[ c_{-4} = -0.877910629139006 \]

\[ c_{-3} = 0.127857696605495 \]

\[ c_{-2} = 1.054541418880270 \]

\[ c_{-1} = 1.087386803133082 \]

\[ c_0 = 0.247680298288321 \]

\[ c_1 = -0.50612992523331 \]
2. The given boundary value problem is,

\( u'' + u = 0; \quad u(0) = 1 \text{ and } u'(1) = 0 \)

The exact solution is,

\[ u(x) = \cos x + \tan 1 \sin x \]

\[ c_{-5} = -16.784099470868910 \]

\[ c_{-4} = -15.622648376150911 \]

\[ c_{-3} = -8.883687788040305 \]

\[ c_{-2} = -3.026098858023991 \]

\[ c_{-1} = 0.579267070363675 \]

\[ c_0 = 1.960144587700136 \]

\[ c_1 = 1.418474146775382 \]

3. The given boundary value problem is,

\( u'' + u = 0; \quad u(0) = 1 \text{ and } u'(1) + u(1) = 0 \)

The exact solution is,

\[ u(x) = \cos x + (\tan 2 - \sec 2) \sin x \]
\[ c_{-5} = -13.541294401791857 \]
\[ c_{-4} = -12.126299651408310 \]
\[ c_{-3} = -6.346329455749815 \]
\[ c_{-2} = -1.657781810857689 \]
\[ c_{-1} = 0.790083941059115 \]
\[ c_0 = 1.133626147467154 \]
\[ c_1 = 0.186034129844783 \]

Fig.4: Wavelet-Galerkin Solution for \( u'' + u = 0; \ u(0) = 1 \) and \( u'(1) + u(1) = 0 \)

VII. CONCLUSIONS

Wavelet method has shown a very powerful numerical technique for the stable and accurate solution of given boundary value problem. The comparison shows that the exact solution correlates with numerical solution, using Daubechies wavelets.
